

ABSTRACT

A method for use in generating a set of transform rules to be used in transforming existing web pages (or other information) for display (or playback, or the like) on associated web enabled Internet appliances. Information in a source page and a template page are identified as elements with an identifier and path name. User actions for arranging the elements are recorded are recorded onto at least a pair of stacks, which might include a redo stack, and an undo stack. The stacks are used as the basis for supporting the user actions. Chains of elements are generated from the stacks, and XSLT is provided from the chains. XSLT is associated with the transform rules, which reference the XSLT. The set of transform rules for the source pages are generated according to the source page URL, the XSLT, and the intended receiving device.
